

Single Pendulum, named two-physical-state profile: saved four-method bounds

x1: all 100 saved tube intervals

x2: all 100 saved tube intervals

x1: endpoint difference from Huan, $t = 0.8-1$

x2: endpoint difference from Huan, $t = 0.8-1$

Huan and Xiangru saved bounds coincide exactly. Lower panels subtract Huan bounds; solid = lower, dashed = upper. Shading marks x_1 target $[0,1]$, checked on $t = 0.5-1$. Official three-state MATLAB identity remains unresolved. Axis projections are not an independent NNCS certificate.
